Training naïve Bayes

To train your naïve Bayes classifier, you have to perform the following steps:

1) Get or annotate a dataset with positive and negative tweets

2) Preprocess the tweets: `process_tweet(tweet) → [w1, w2, w3, ...]`:

- Lowercase
- Remove punctuation, urls, names
- Remove stop words
- Stemming
- Tokenize sentences

3) Compute `freq(w, class)`:

Positive tweets

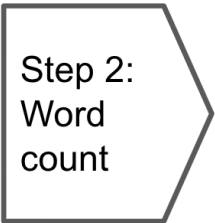

[happi, because, learn, NLP]

[happi, not, sad]

Negative tweets

[sad, not, learn, NLP]

[sad, not, happi]

word	Pos	Neg
happi	2	1
because	1	0
learn	1	1
NLP	1	1
sad	1	2
not	1	2

N_{class} 7 7

`freq(w, class)`

4) Get $P(w|pos), P(w|neg)$

You can use the table above to compute the probabilities.

5) Get $\lambda(w)$

$$\lambda(w) = \log \frac{P(w|pos)}{P(w|neg)}$$

6) Compute $logprior = \log(P(pos)/P(neg))$

$logprior = \log \frac{D_{pos}}{D_{neg}}$, where D_{pos} and D_{neg} correspond to the number of positive and negative documents respectively.
